DECLARATION

We declare that this is our own work, and this proposal does not incorporate without acknowledgement any material previously submitted for a degree or diploma in any other university or Institute of higher learning and to the best of our knowledge and belief it does not contain any material previously published or written by another person except where the acknowledgement is made in the text.

NAME	Student ID	Signature
H.P.R.D.Thilina Wickramarathna	IT22571984	

The supervisor/s should certify the proposal report with the following declaration. The above candidates are carrying out research for the undergraduate Dissertation under my supervision.

.....

Signature of the supervisor:

Date: 8/31/2025

ACKNOWLEDGMENT

I could not have finished this research without the consistent help of our supervisors, Ms. Lokesha Weerasinghe and Prof. Dilshan De Silva, Instructor, Department of Information Technology, Sri Lanka Institute of Information Technology. They helped us overcome our mistakes and provided insightful feedback, which has enabled me to make my project a success and produce more effective results. I also want to thank our panel members for their insightful counsel, which helped me understand the shortcomings of the research and suggest methods to make it more useful.

Additionally, I would like to thank the coordinators, the course's comprehensive design and analysis instructor, for providing us with the necessary support during this project module, which allowed me to successfully solve the issues we ran across. Lastly, I would like to thank everyone who provided me with either direct or indirect assistance in finishing this study. Your suggestions and tremendous assistance motivated me to complete this work.

ABSTRACT

Exam stress has become a significant concern among students, affecting both academic performance and mental well-being. Sri Lankan G.C.E. Ordinary Level (O/L) students experience high levels of pressure due to heavy academic workloads and competitive examinations. Traditional stress management approaches are largely reactive and lack the ability to predict stress before it escalates. Therefore, there is a growing need for a proactive solution that can identify stress levels early and provide practical guidance.

This research proposes an AI-powered Exam Stress Level Prediction System designed to assess students' stress levels—categorized as Low, Medium, or High—before major exams. The system considers multiple factors, including term test averages, attendance, homework completion, study hours, sleep duration, and pending assignments, to evaluate stress risk. Based on the identified stress level, the system will provide personalized recommendations to help students manage their time effectively, balance workload, and adopt healthier study habits.

The goal of this solution is to reduce exam-related stress and support students in maintaining both academic success and mental well-being. By delivering early warnings and actionable advice, this system aims to create a positive learning environment for Sri Lankan students preparing for critical examinations.

Keywords: Exam stress prediction, student well-being, education support system, AI/ML

1. INTRODUCTION

Exams are an essential component of education, particularly in competitive systems like the O/L. in Sri Lanka. Exam stress has emerged as a hidden factor influencing performance and general well-being, even though academic performance is the main indicator of success. Lack of sleep, a heavy workload, and ongoing stress can all impair motivation, memory, and focus, which lowers academic performance.

Conventional methods for identifying stress depend on self-reporting or teacher observation, both of which are frequently arbitrary and unreliable. The development of machine learning (ML) and artificial intelligence (AI) has made it feasible to use data-driven techniques to more precisely forecast stress levels. ML models can categorize students into Low, Medium, or High stress groups by looking at patterns like study hours, assignment completion, sleep duration, attendance, and short-term test scores.

The proposed Exam Stress Level Prediction component provides a proactive solution to identify students at risk before major exams. This system will not only generate predictions but also recommend personalized strategies such as balanced study plans, adequate rest, and revision focus. Ultimately, this tool helps students, teachers, and parents reduce exam anxiety, improve performance, and promote mental well-being in academic settings.

1.1. BACKGROUND & LITERATURE SURVEY

1.1.1 Background

Examinations have long been recognized as one of the primary methods to assess a student's academic performance. However, the pressure associated with these exams has become a major source of psychological stress among students globally. Academic stress

refers to the emotional strain resulting from academic demands, time pressure, and high expectations from parents, teachers, and society. Studies indicate that excessive stress not only affects mental health but also reduces academic performance, leading to issues such as anxiety, depression, poor concentration, and lack of motivation [1].

In the Sri Lankan education system, the General Certificate of Education Ordinary Level (G.C.E. O/L) examination is considered a decisive milestone in a student's academic journey. The outcome of this examination significantly influences access to Advanced Level streams and future career opportunities [2]. Due to the competitive nature of this examination, students are subjected to long study hours, numerous tuition classes, and constant pressure to excel. These factors contribute to heightened stress levels, especially during the months leading up to the exams.

Currently, most stress management methods in Sri Lanka focus on traditional approaches such as counseling sessions, mindfulness programs, and parental guidance. While these methods are beneficial, they are generally reactive, addressing the problem only after stress has reached a critical level. In addition, there is a lack of systematic tools or mechanisms in schools to monitor and predict stress levels before examinations. With the growing integration of technology in education, there is an opportunity to leverage data-driven approaches to identify stress early and recommend preventive measures. This research aims to fill that gap by introducing an intelligent system that can predict stress levels among O/L students and provide actionable recommendations to help maintain a healthy balance between academic performance and mental well-being.

1.1.2 Literature Survey

Stress Measurement and Psychological Impact

Student stress has been extensively studied in educational psychology, with instruments such as the Perceived Stress Scale (PSS) and the Depression, Anxiety, and Stress Scale [3] widely recognized as reliable measures for adolescents and young adults [4]. These tools provide quantifiable indicators of psychological strain, essential for empirical studies and early interventions. High academic pressure has been shown to impair cognitive functioning, particularly memory, concentration, and decision-making, leading to reduced learning outcomes and long-term mental health challenges [5].

In South Asia, societal and parental expectations significantly amplify exam-related stress, where academic achievement is often tied to family reputation and future opportunities [6]. In Sri Lanka, this is especially evident during the G.C.E. O/L examination, which serves as a critical milestone for academic progression [7]. As a result, many students experience heightened anxiety, sleep disturbances, and psychosomatic symptoms in the months preceding exams.

Behavioral and Academic Indicators of Stress

Global and local studies emphasize the influence of lifestyle and academic behaviors on stress levels. Sleep deprivation is strongly associated with reduced academic performance, poor emotional regulation, and increased susceptibility to anxiety [8]. Students sleeping less than 6–7 hours during exam preparation demonstrate lower cognitive flexibility compared to peers with healthy sleep routines.

Similarly, workload intensity, including the number of pending assignments and frequent tests, correlates with elevated stress [5]. Students facing multiple subject deadlines often

report feelings of burnout. Study habits also matter—last-minute cramming is linked to higher physiological stress compared to consistent study patterns. Attendance and homework completion rates further influence academic outcomes and mental well-being [9].

AI and Machine Learning for Stress Prediction

In Educational Data Mining (EDM), predictive models such as logistic regression, random forests, and support vector machines (SVM) are widely applied to identify at-risk students using features like attendance, grades, and LMS activity [10]. While advanced solutions using wearables exist, they are often cost-prohibitive for schools. Studies indicate that effective stress prediction can be achieved using simple, low-cost inputs such as sleep duration, study hours, and assignment data [11].

Integrated Well-Being Systems

Recent research argues that predictive analytics should be complemented by actionable recommendations [11]. Systems that provide personalized guidance—including study schedules, sleep recommendations, and stress management tips—have demonstrated improved student engagement [12]. International case studies from Finland, Singapore, and India show the success of holistic dashboards combining academic and behavioral metrics [13]. However, such systems remain scarce in Sri Lanka, where stress management is still largely limited to traditional counseling.

Data and Platform Considerations for Schools

Cost-effective solutions often rely on existing data sources like gradebooks, attendance logs, and basic self-reports, avoiding the need for specialized devices [11]. Tree-based models are popular due to their robustness on small datasets and their ability to explain predictions in an interpretable manner [10].

1.2. RESEARCH GAP

Many previous studies have explored student stress using standardized psychological scales such as the Perceived Stress Scale (PSS) and DASS-21, but these methods are mainly survey-based and do not integrate academic or lifestyle factors. Some research explores the influence of sleep, study hours, and workload on stress, while others use machine learning models mainly for academic prediction rather than psychological well-being. However, these approaches are often limited to university students or general adolescent groups, with little focus on Sri Lankan O/L students.

International projects have developed student well-being dashboards that combine multiple indicators and provide recommendations, but such integrated systems are not available in Sri Lanka. Existing approaches also lack personalized feedback that helps students balance study schedules, sleep patterns, and workload.

The proposed system fills this gap by combining validated stress scales with academic and lifestyle data, applying machine learning models to predict stress levels, and delivering personalized recommendations specifically for Sri Lankan O/L students. This makes it both a predictive and preventive tool for exam stress management in the local school context.

Features	Stress Measured with Scales (PSS/DASS)	Academic & Lifestyle Factors (Sleep, Study Hours, Assignments, Attendance)	AI/ML Prediction Models (RF, SVM, etc.)	Focus on School-Level (O/L) Students	Personalized Recommendations (Study–Sleep Balance, Workload Mgmt.

Table 2.1: Research gap table

Lack of Psychological Well-Being Integration

Most existing school and e-learning monitoring systems mainly track grades, test scores, and attendance to evaluate student performance. However, they neglect key psychological stress factors such as study workload, sleep quality, and pending assignments, which directly affect exam readiness and student well-being. The proposed system integrates both academic and behavioral inputs to predict stress levels more holistically.

Limited Use of AI/ML for Stress Prediction

Although machine learning models are widely applied in predicting exam results or dropout risks, AI-driven stress classification remains underexplored—especially at the school level. Few systems use supervised learning algorithms (Random Forest, SVM) to classify students into Low, Medium, or High stress categories. Our research addresses this by designing a dedicated AI-based classification model for exam stress prediction.

Lack of Personalized Interventions

Current predictive systems often stop at identifying “at-risk” students without offering personalized recommendations. This limits their practical usefulness in reducing exam stress. The proposed system goes further by providing customized advice, such as adjusting study hours, improving sleep schedules, or managing workload, tailored to each student’s unique stress profile.

Contextual Gap in Sri Lankan O/L Education

Most prior research focuses on university students or Western school systems. Very little work has been done in Sri Lanka’s O/L context, where students face intense cultural, parental, and societal

pressure to perform well in high-stakes national exams. Our system is designed specifically for the Sri Lankan O/L setting, making it culturally and contextually relevant.

Limited Real-World Implementations

While theoretical models and international case studies exist, practical, school-level implementations in Sri Lanka remain scarce. Few systems are designed to be affordable, scalable, and easy-to-use with limited resources in schools. Our research closes this gap by developing a low-cost, school-adaptable prototype that uses data already collected in schools (marks, attendance, self-reports).

1.3 RESEARCH PROBLEM

The General Certificate of Education Ordinary Level (G.C.E. O/L) examination is a critical milestone in the Sri Lankan education system, shaping access to higher education and influencing future career pathways. However, O/L students often face intense academic and psychological pressure, driven by heavy workloads, long study hours, tuition commitments, and high parental expectations. This sustained pressure frequently results in elevated stress levels that negatively impact memory, focus, motivation, and ultimately academic performance. Prolonged or unmanaged stress has also been linked to burnout, absenteeism, and reduced overall well-being among adolescents.

Despite the significance of exam stress, most Sri Lankan schools lack structured mechanisms to monitor or predict stress levels. Schools typically collect academic data such as test scores, attendance, and homework completion, but these metrics alone do not reflect a student's psychological state. Teachers and parents often identify stress only after its negative effects appear, by which time interventions may be too late to prevent academic decline. Existing performance dashboards in schools focus narrowly on academic outcomes, overlooking behavioral indicators like study hours, sleep patterns,

pending assignments, and short-term performance fluctuations, which are directly correlated with exam stress.

Globally, some advanced stress detection solutions exist, but these often rely on wearable devices, biometric sensors, or cloud-based platforms. Such approaches are impractical in Sri Lanka due to cost, infrastructure limitations, and privacy concerns. Moreover, most existing predictive systems are designed for university-level or Western education contexts, making them unsuitable for the cultural and academic environment of Sri Lankan O/L students.

The research problem, therefore, is the absence of an affordable, AI/ML-based framework specifically tailored for Sri Lankan O/L students that can proactively predict exam stress levels by integrating academic, behavioral, and workload-related data. Without such a solution, exam stress remains an invisible barrier that undermines both academic performance and student well-being. This research aims to fill that gap by developing a predictive model that not only categorizes students into Low, Medium, or High stress levels but also generates personalized, actionable recommendations to help them manage workload, balance study and sleep, and maintain psychological well-being during high-stakes exam preparation.

1.4 Research Questions

1. How can AI/ML techniques be applied to predict exam stress levels among Sri Lankan O/L students using academic and behavioral data?
2. What are the key academic, behavioral, and workload-related features (e.g., study hours, sleep, assignment load, recent test marks) that most strongly influence exam stress prediction?
3. Can a predictive model classify students into Low, Medium, and High stress categories with acceptable accuracy for real-world school environments?
4. How effective are personalized recommendations generated from the model in helping students reduce exam stress and improve study efficiency?
5. What implementation approach (offline system, lightweight dashboard, or web-based tool) is most practical and feasible for adoption in Sri Lankan schools with limited resources?

2.OBJECTIVES

2.1 Main Objectives

The main objective of this research is to develop an AI-powered Exam Stress Level Prediction system specifically tailored for Sri Lankan G.C.E. O/L students, which integrates academic data (such as test scores, attendance, and assignment records) with behavioral and lifestyle factors (including study hours, sleep patterns, and workload). The system aims to classify students into Low, Medium, or High stress categories using machine learning techniques and deliver personalized, evidence-based recommendations to help students effectively manage their study schedules, maintain healthy routines, and enhance overall academic performance and psychological well-being.

2.2 Specific Objectives

1. **To identify and collect relevant academic and behavioral data** (such as study hours, sleep duration, pending assignments, attendance, and recent test marks) from students through self-reports, school records, and learning management systems.
2. **To preprocess and engineer features** by combining academic and lifestyle factors into meaningful indicators (e.g., study–sleep ratio, workload index, and performance trends) suitable for machine learning analysis.
3. **To design and train machine learning models** (Random Forest, SVM, etc.) capable of classifying students into Low, Medium, and High stress levels with acceptable accuracy for real-world school environments.
4. **To develop a recommendation module** that generates personalized, evidence-based guidance (e.g., balanced study plans, sleep improvement, workload management) aligned with each student’s predicted stress level.

5. **To evaluate the effectiveness of the proposed system** through accurate testing of the prediction model, user acceptance feedback, and validation of recommendations in improving study efficiency and reducing exam stress.

3.METHODOLOGY

The methodology of this research defines the structured process followed to design, develop, and validate the proposed Exam Stress Level Prediction system. This approach integrates academic data, behavioral indicators, and lifestyle factors with artificial intelligence and machine learning techniques to proactively predict stress levels among Sri Lankan G.C.E. O/L students. The methodology is designed not only to ensure the **accuracy of stress classification** but also to guarantee that the system provides **practical and meaningful recommendations** to reduce exam-related stress.

3.1. System Diagram

Figure 3.1 : Overall System Architecture

Figure 3.1 : System Architecture of the Exam Stress Level Prediction System

3.2. Technology and Tool Selection

3.2.1. Technologies

The successful development of the Exam Stress Level Prediction system depends on the appropriate selection of technologies and tools that ensure efficiency, scalability, and reliability. Since the system integrates academic and behavioral data with machine learning models, the chosen tools must support data preprocessing, model training, visualization, and deployment within a lightweight educational environment.

Technology	Purpose	Pros	Cons	Suitability
Python	Core programming language	Rich ML ecosystem (Scikit-learn, TensorFlow, Pandas), easy learning curve	Slower execution speed compared to C/Java	High – best fit for ML-based research
Scikit-learn	Machine learning (classical models)	Simple API, efficient for small/medium datasets, interpretable models	Limited deep learning support	High – suitable for stress classification
TensorFlow/Keras	Prototype data storage	Easy to handle, portable, no setup required	Not scalable for large datasets	High – good for prototype phase

Matplotlib/Seaborn	Data visualization	Open source, integrates with Python ML pipelines	Less interactive compared to BI tools (Tableau/Power BI)	High – ideal for a research prototype
Flask	Web framework (prototype dashboard)	Lightweight, easy to deploy, integrates with Python	Less suitable for large-scale enterprise applications	High (supports analytics)

Table 3.1: Technology and Tool

4.PROJECT REQUIREMENTS

4.1 Functional Requirements

1. Student Data Collection

The system will provide multiple ways for students and teachers to input academic and behavioral data. This includes term test marks, study hours, attendance records, homework completion, and pending assignments.

Data can be entered manually through online forms or uploaded in bulk using CSV files. This flexibility ensures both small-scale and large-scale data entry is efficient and consistent.

2. Data Preprocessing & Normalization

Raw data often contains missing or inconsistent values that reduce accuracy. The system will automatically handle these issues by applying data cleaning, normalization, and error-checking methods.

In addition, derived indicators such as **workload index** and **study-to-rest ratio** will be generated. These features will enrich the dataset, making predictions more meaningful and reliable.

3. Stress Level Classification

The system will classify student stress into three categories: Low, Medium, and High. This will be done using proven machine learning algorithms such as Random Forest and Support Vector Machine (SVM).

By training on academic and behavioral data, the system ensures predictions are both accurate and interpretable. This provides valuable insights for teachers, parents, and students.

4. Trend Analysis Module

Stress levels are not static—they fluctuate over time based on workload and study habits. The system will track these changes by comparing recent inputs with historical records. This allows identification of **patterns and warning signs**, helping educators intervene early. Trend graphs will highlight increasing stress before it becomes critical.

5. Personalized Recommendation Generation

The system shall generate actionable recommendations based on stress classification results.

6. Visualization Dashboard

A user-friendly web dashboard will present predictions in a clear and engaging way. Stress levels will be displayed with color-coded indicators (Green = Low, Yellow = Medium, Red = High). Alongside this, interactive charts will display study hours, marks, attendance, and stress trends over time. This makes the system results easy to understand at a glance.

7. Alert & Notification System

The system should notify teachers when more than 30% of a class is predicted as High Stress, and alert students individually with personalized recommendations.

8. **Report Generation**

The system shall generate downloadable PDF/Excel reports summarizing each student's stress level, history of predictions, and recommended actions.

9. **Data Security & Privacy**

The system shall ensure that all student data is stored securely, accessible only by authorized users, and anonymized when generating aggregated class-level reports.

4.2 Non-Functional Requirements

1. **Performance**

The system shall process student data (marks, study hours, attendance, homework) within **2–3 seconds** of submission. Real-time response ensures teachers and students can act immediately without delays. This performance will be monitored to remain consistent across devices and networks. Fast operation is crucial during high usage periods such as exam preparation.

2. **Accuracy**

The ML model shall achieve **75–80% accuracy** when classifying stress levels (Low, Medium, High). Accuracy will be validated against historical school data for reliability. Periodic retraining will improve predictions as new data is collected. This ensures educators and parents can trust the system's insights

3. **Scalability**

The system shall support input from at least 500 students simultaneously without performance drops. This makes the solution adaptable to both small schools and large educational institutions.

4. **Usability**

Dashboards shall use **simple language and visuals** understandable to O/L and A/L students. Teachers will access class-level views for easier monitoring. Clear design will improve accessibility and reduce learning effort. The system will prioritize simplicity to maximize adoption

5. **Security**

Student data (marks, attendance, study patterns) shall be stored securely with restricted access control and compliance with basic data privacy standards.

6. **Reliability**

The system shall ensure 99% uptime during school operating hours and function properly without internet connectivity if offline mode is enabled. The system shall maintain 99% uptime during school hours. An offline mode will ensure continued use without internet.

7. **Maintainability**

The system codebase shall be modular and documented to allow future updates (e.g., adding new features like sleep tracking).

8. **Portability**

The system shall be deployable on multiple platforms (local school servers, cloud hosting, or desktop PCs) with minimal configuration. Portability enables use across urban and rural schools.

9. **Visualization Quality**

Graphs, charts, and stress-level indicators shall use color coding (green = Low, yellow = Medium, red = High) for intuitive understanding. Visuals will avoid technical jargon for easy interpretation.

4.3 System requirements

1. Python – For implementing machine learning models (scikit-learn, pandas, NumPy) and data preprocessing.
2. FastAPI / Flask – To build the backend API for stress prediction and communication with the frontend.
3. VS Code – As the main Integrated Development Environment (IDE) for coding and debugging.
4. React / React Native – To design a user-friendly, cross-platform web or mobile application for students, teachers, and parents.
5. MongoDB / MySQL – Database to store student data (marks, attendance, assignments, stress records).
6. Node.js – To manage the server-side logic and API integrations with the frontend.
7. Git & GitHub – For version control and collaborative development.
8. Jupyter Notebook – For testing, training, and visualizing ML models during development.

4.4 User Requirements

1. Students:

- Enter their study hours, sleep hours, and assignment status.
- View predicted stress level (Low/Medium/High).
- Receive simple recommendations to manage stress.

2. Teachers:

- Monitor students' stress levels.
- Get alerts for high-stress students.
- Support students with early interventions.

3. Parents:

- Check their child's stress status.
- Follow recommendations to help reduce exam stress.

4. School Management:

- Analyze overall class or school stress patterns.

4.4 Expected Test Cases

Test Case 1: Stress Level Prediction from Marks

- **Input:** Term marks drop by more than 20% compared to previous term.
- **Expected Output:** System classifies student stress as **High** and generates recommendation: *"Reduce workload, seek teacher guidance."*

Test Case 2: Stress Prediction with Balanced Performance

- **Input:** Marks remain stable ($\pm 5\%$), attendance above 90%, all homework submitted.
- **Expected Output:** System classifies stress as **Low** and recommendation: *"Maintain current study habits."*

Test Case 3: Homework Non-Compliance

- **Input:** Homework submission rate $< 50\%$ in last 2 weeks, study hours > 5 per day.
- **Expected Output:** Stress level **Medium**, recommendation: *"Prioritize homework completion, balance study hours."*

Test Case 4: High Attendance but Low Marks

- **Input:** Attendance 95%+, but two major subjects show continuous decline.

- **Expected Output:** Stress level **High**, recommendation: *“Focus on weak subjects, seek tutoring support.”*

Test Case 5: System Performance

- **Input:** Data upload for 300 students simultaneously.
- **Expected Output:** Predictions generated in **under 3 seconds** per student.

Test Case 6: Usability

- **Input:** Student views dashboard on school PC.
- **Expected Output:** Stress level shown with clear **color-coded indicator (Green/Yellow/Red)** and 2–3 actionable suggestions.

Test Case 7: Security Check

- **Input:** Unauthorized user attempts to access student records.
- **Expected Output:** System denies access and logs security breach attempt.

5. GANTT CHART

Figure 5.1: Gantt chart

5.1 WORK BREAKDOWN STRUCTURE

Figure 5.2 : Work Breakdown Structure

5.2 Budget Breakdown

Component	Cost (RS)	Quantity	Total (RS)
Laptop/PC (for development & model training)	210,000	1	210,000
Cloud Hosting (API & Dashboard – 6 months)	9000/month	6	54000
Data Storage & Backup (Cloud Database)	3000/month	6	18000
Python Libraries & Dependencies	Free	-	0
Web Hosting (Frontend Deployment)	4500/month	6	27000
Visualization Tools (Plotly, Chart.js)	Free	-	\$0
Miscellaneous (electricity, internet, stationery)	15000	1	15000

Table 5.1: Project budget breakdown

6. COMMERCIALIZATION POTENTIAL & ENTREPRENEURSHIP

6.1 Market Analysis and Business Potential

Target Market Size:

- Sri Lankan Secondary Students (O/L): ~700,000 students annually
- South Asian Region: Over **50 million exam-taking students** (India, Pakistan, Bangladesh, Sri Lanka)
- Global Market (Developing & Developed Countries): Estimated **200+ million secondary and tertiary students** facing exam-related stress

Market Value Proposition: The proposed system addresses a **critical educational need** with strong commercialization potential through measurable user benefits:

1. **Cost-Effective Stress Monitoring:** Automated AI-based tool reduces reliance on costly human-only interventions.
2. **Improved Academic Outcomes:** Early detection and management of exam stress increases pass rates and reduces dropout risk.
3. **Scalable Solution:** Easily integrated with existing school databases or LMS without expensive infrastructure.
4. **Well-Being Enhancement:** Supports student mental health initiatives and aligns with global education wellness standards (UNESCO/WHO guidelines).
1. **Data Analytics Services:** Optional \$50–\$100 monthly per institution for aggregated insights into student well-being trends.

Go-to-Market Strategy:

- **Phase 1:** Pilot deployment in 2–3 leading Sri Lankan schools and tuition centers (proof of concept).

Economic Impact:

- Potential to reduce exam-related student dropouts and failures by 20–30%, improving national education outcomes.
- Support mental health initiatives by providing early intervention insights for teachers and parents.
- Job creation opportunities in AI system training, school IT support, and counselor upskilling.
- Long-term economic benefits from producing healthier, more resilient students who perform better in higher education and careers
